# **COMPUTER SECURITY**

## **Symmetric Cryptography in Practice**

GALLOGLY COLLEGE OF ENGINEERING  
SCHOOL OF COMPUTER SCIENCE  
*The* UNIVERSITY of OKLAHOMA

# OUTLINE LAST TIME

- “Key” issues
  - Secret key cryptography
  - Public key cryptography
  - Hash
- Security Metrics
  - Perfect Security
  - Today’s cryptographic systems do not achieve perfect security.
- P and NP problems
  - P: The set of questions that can be solved in polynomial time
  - NP: the set of questions for which an answer can be verified in polynomial time
  - Modern Cryptography: Without the key, the adversary must solve an NP problem, where a solution in P with polynomial time is “currently believed very hard” to find.

# SECRET KEY CRYPTOGRAPHY

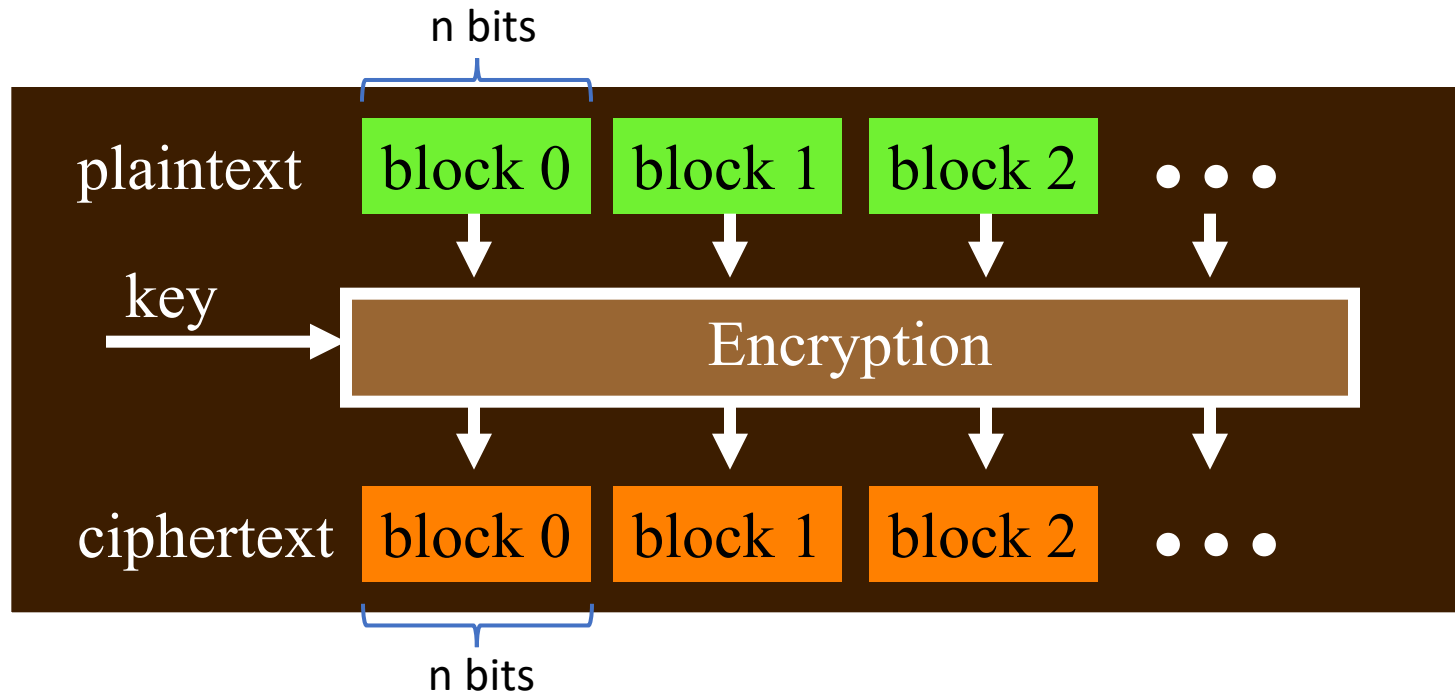

- Same key is used for both encryption and decryption
  - This one key is shared by two parties who wish to communicate securely
- Also known as *symmetric key cryptography*, or *shared key cryptography*

# APPLICATIONS OF SECRET KEY CRYPTO

- Communicating securely over an insecure channel
  - Alice encrypts using shared key
  - Bob decrypts result using same shared key
  
- *Authentication*
  - Bob can verify if a message is generated by Alice

# GENERIC BLOCK ENCRYPTION

- Converts one input plaintext block of fixed size  $n$  bits to an output ciphertext block also of  $n$  bits

# KEY SIZES

- A Key should be selected from a large potential set to prevent brute force (exponential-time) attacks
  - If a key is of 3 bits, what are the possible keys?
    - 000, 001, 010, 011, 100, 101, 110, 111
  - Given a pair of (plaintext, ciphertext), an attacker can do a brute force !

Question: If a key is of  $n$  bits, how many possible keys does a brute force attacker need to search?

# KEY SIZES (CONT'D)

- Secret key sizes
  - 40 bits were considered adequate in 70's
  - 56 bits used by DES were adequate in the 80's
  - 128 bits are adequate for now
    - $2^{128} \approx 3.4E + 38$
    - If a computer can finish **1 billion searches** per second, it requires **3938453320844195178974243 years**
  - 256 bits are also used now

# KEY SIZES (CONT'D)

- Brute-force attack: try all combinations
  - NP problem: currently, the time increases exponentially as the key size increases.
- The computing power
  - Increases approximately linearly
- If computers increase in power by **40%** per year, need roughly **5 more key bits** per decade to stay “sufficiently” hard to break

# SOME MOTIVATIONS

---

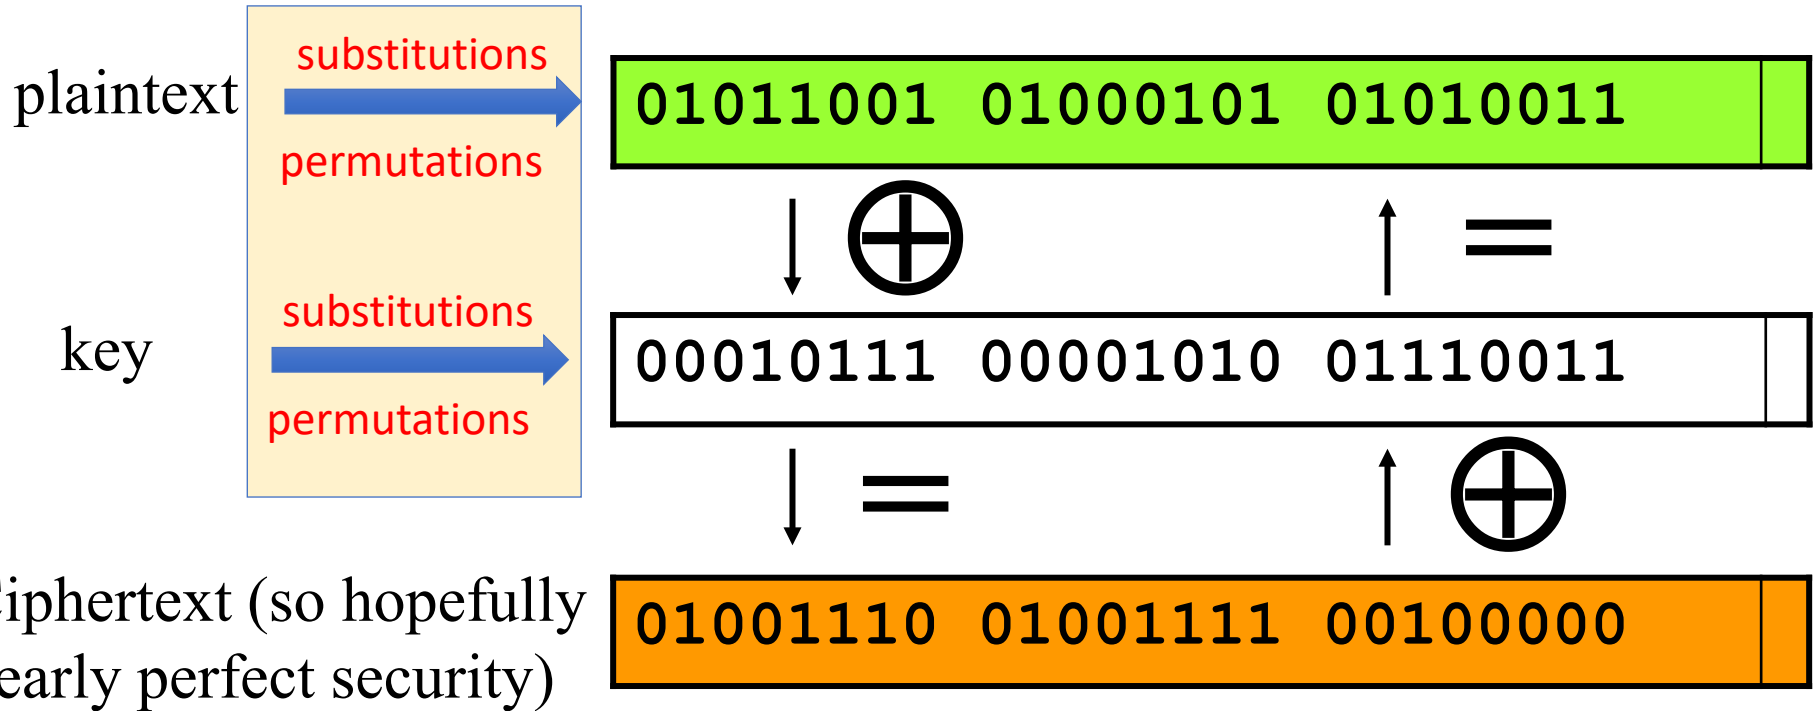

- How to design the ciphers?

# SOME MOTIVATIONS

- Early ciphers:
  - Using substitutions:
    - Ceasar variant, mono-alphabetic, Vigenere, ...
  - Using permutations:
    - permutation ciphers
- One time pad:
  - theory-supported
  - Using XOR
    - plaintext XOR a random key

# FOLLOW SHANNON'S GUIDELINE

make them pseudo random sequences

**Q: Why also need to make the plaintext pseudo random?**

# PRINCIPLES FOR CIPHER DESIGN

- **Confusion:**
  - Make the relationship between the <plaintext, key> input and the < ciphertext> output as complex (non-linear) as possible
  - Confusion is mainly accomplished by **substitutions**
- **Diffusion:**
  - Spread the influence of each input bit across many output bits
  - Diffusion is mainly accomplished by **permutations**

# EXPLOITING THE PRINCIPLES

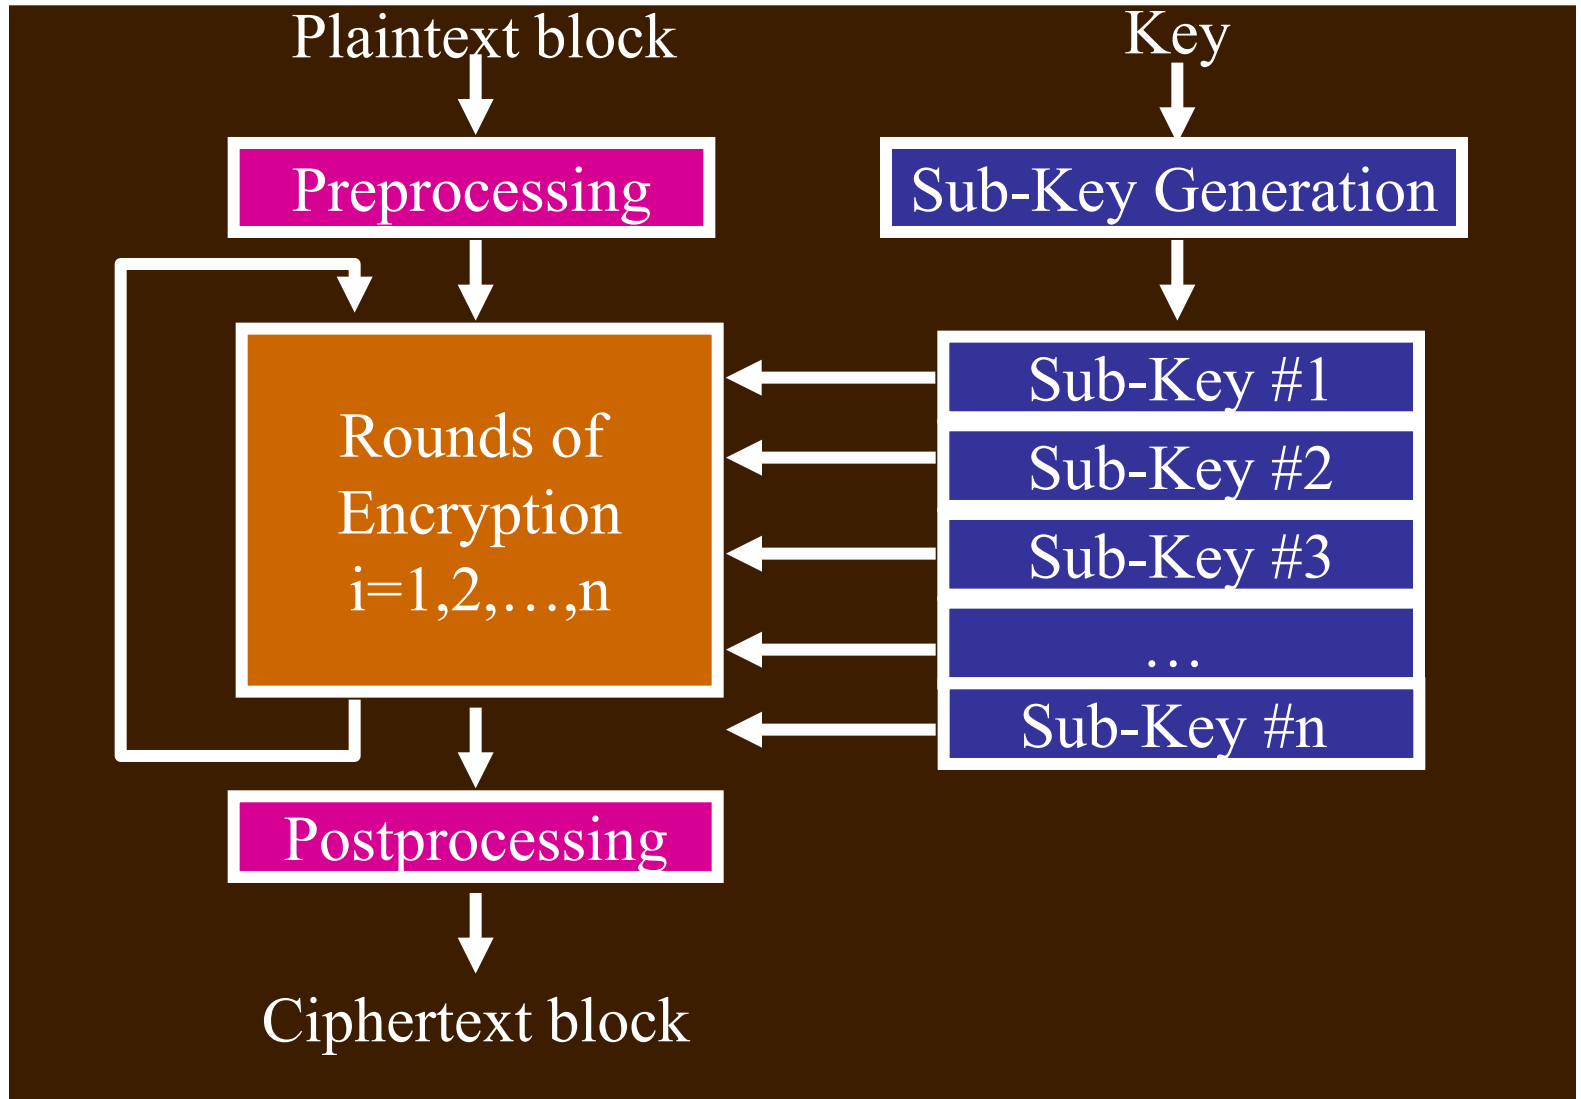

- Idea: use multiple, alternating **P**ermutations and **S**ubstitutions, e.g.,
  - $S \rightarrow P \rightarrow S \rightarrow P \rightarrow S \rightarrow \dots$
  - $P \rightarrow S \rightarrow P \rightarrow S \rightarrow P \rightarrow \dots$
- Do P and S have to alternate? e.g....
  - $S \rightarrow S \rightarrow S \rightarrow P \rightarrow P \rightarrow P \rightarrow S \rightarrow S \rightarrow \dots?$
  - Consecutive Ps or Ss do not improve security
  - Example?

# SECRET KEY... (CONT'D)

- Basic technique used in secret key ciphers: multiple applications of alternating substitutions and permutations

# BASIC FORM OF MODERN BLOCK CIPHERS

# FEISTEL CIPHER

- Feistel Cipher has been a very influential “template” for designing a block cipher
- Major benefit: Encryption and decryption take the same time
  - they can be performed on the same hardware
- Examples: DES, RC5

# ONE "ROUND" OF FEISTEL ENCRYPTION

1. Break input block  $i$  into left and right halves  $L_i$  and  $R_i$
2. Copy  $R_i$  to create output half block  $L_{i+1}$
3. Half block  $R_i$  and key  $K_i$  are "scrambled" by function  $f$
4. XOR result with input half-block  $L_i$  to create output half-block  $R_{i+1}$

Key elements: **substitution**, **XOR**, and **permutation**

# ONE "ROUND" OF FEISTEL DECRYPTION

- Just reverse the arrows!
- Why?

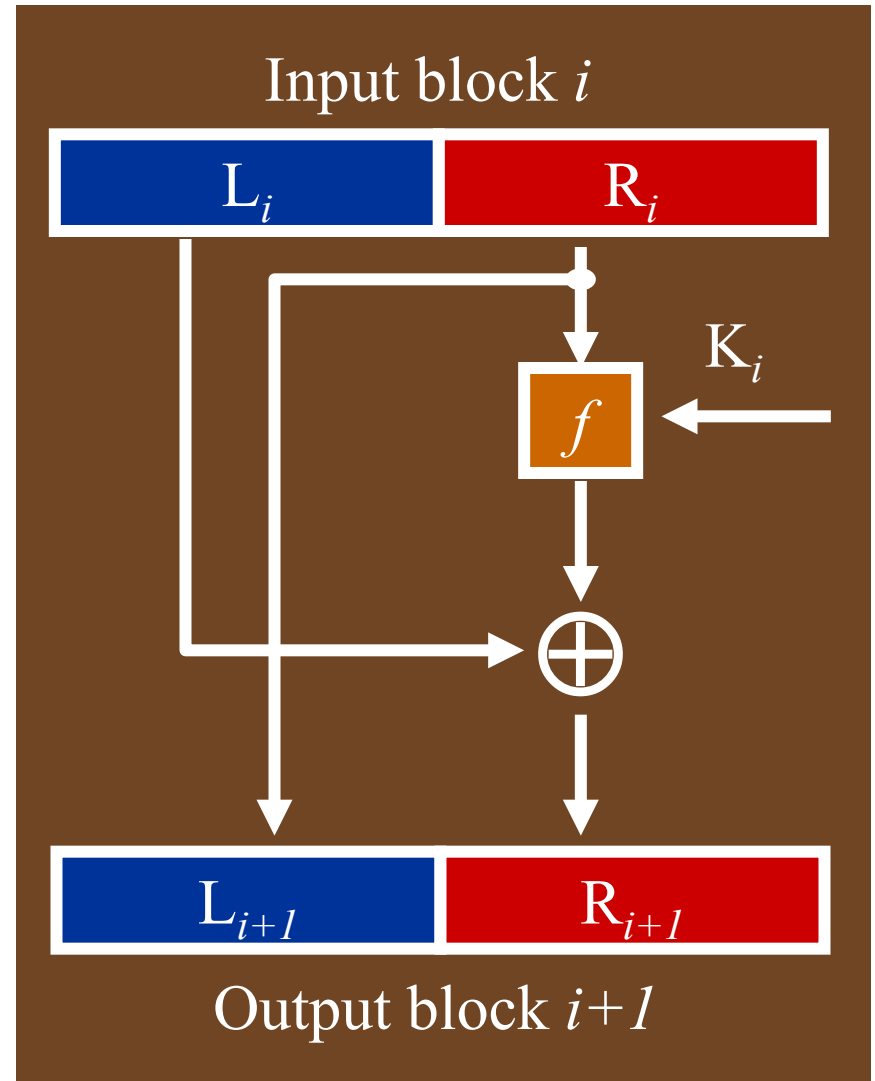

# FEISTEL CIPHER: ENCRYPTION (CONT'D)

- Encryption:

- $L_{i+1} = R_i$

- $R_{i+1} = L_i \oplus f(R_i, K_i)$

# FEISTEL CIPHER: DECRYPTION (CONT'D)

- Decryption:

- $\hat{R}_i = L_{i+1} = R_i$

- $\hat{L}_i = R_{i+1} \oplus f(R_i, K_i)$   
 $= L_i \oplus f(R_i, K_i) \oplus f(R_i, K_i)$   
 $= L_i \oplus \text{all 0 bits} = L_i$

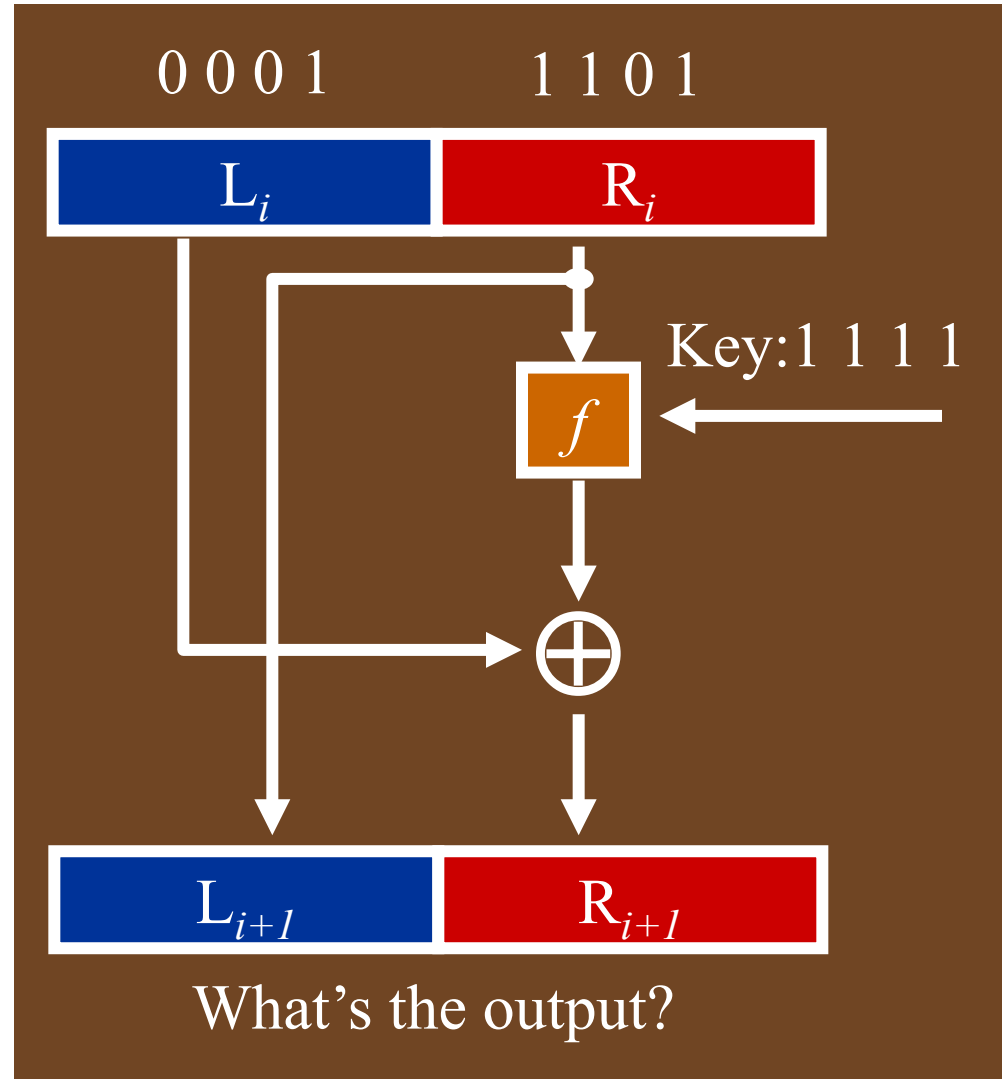

# EXERCISE

Key generation:  
subkey is the key

Scrambling function  
 $f(K, R_i) = K \oplus R_i$

Q: What's the output?

# EXERCISE

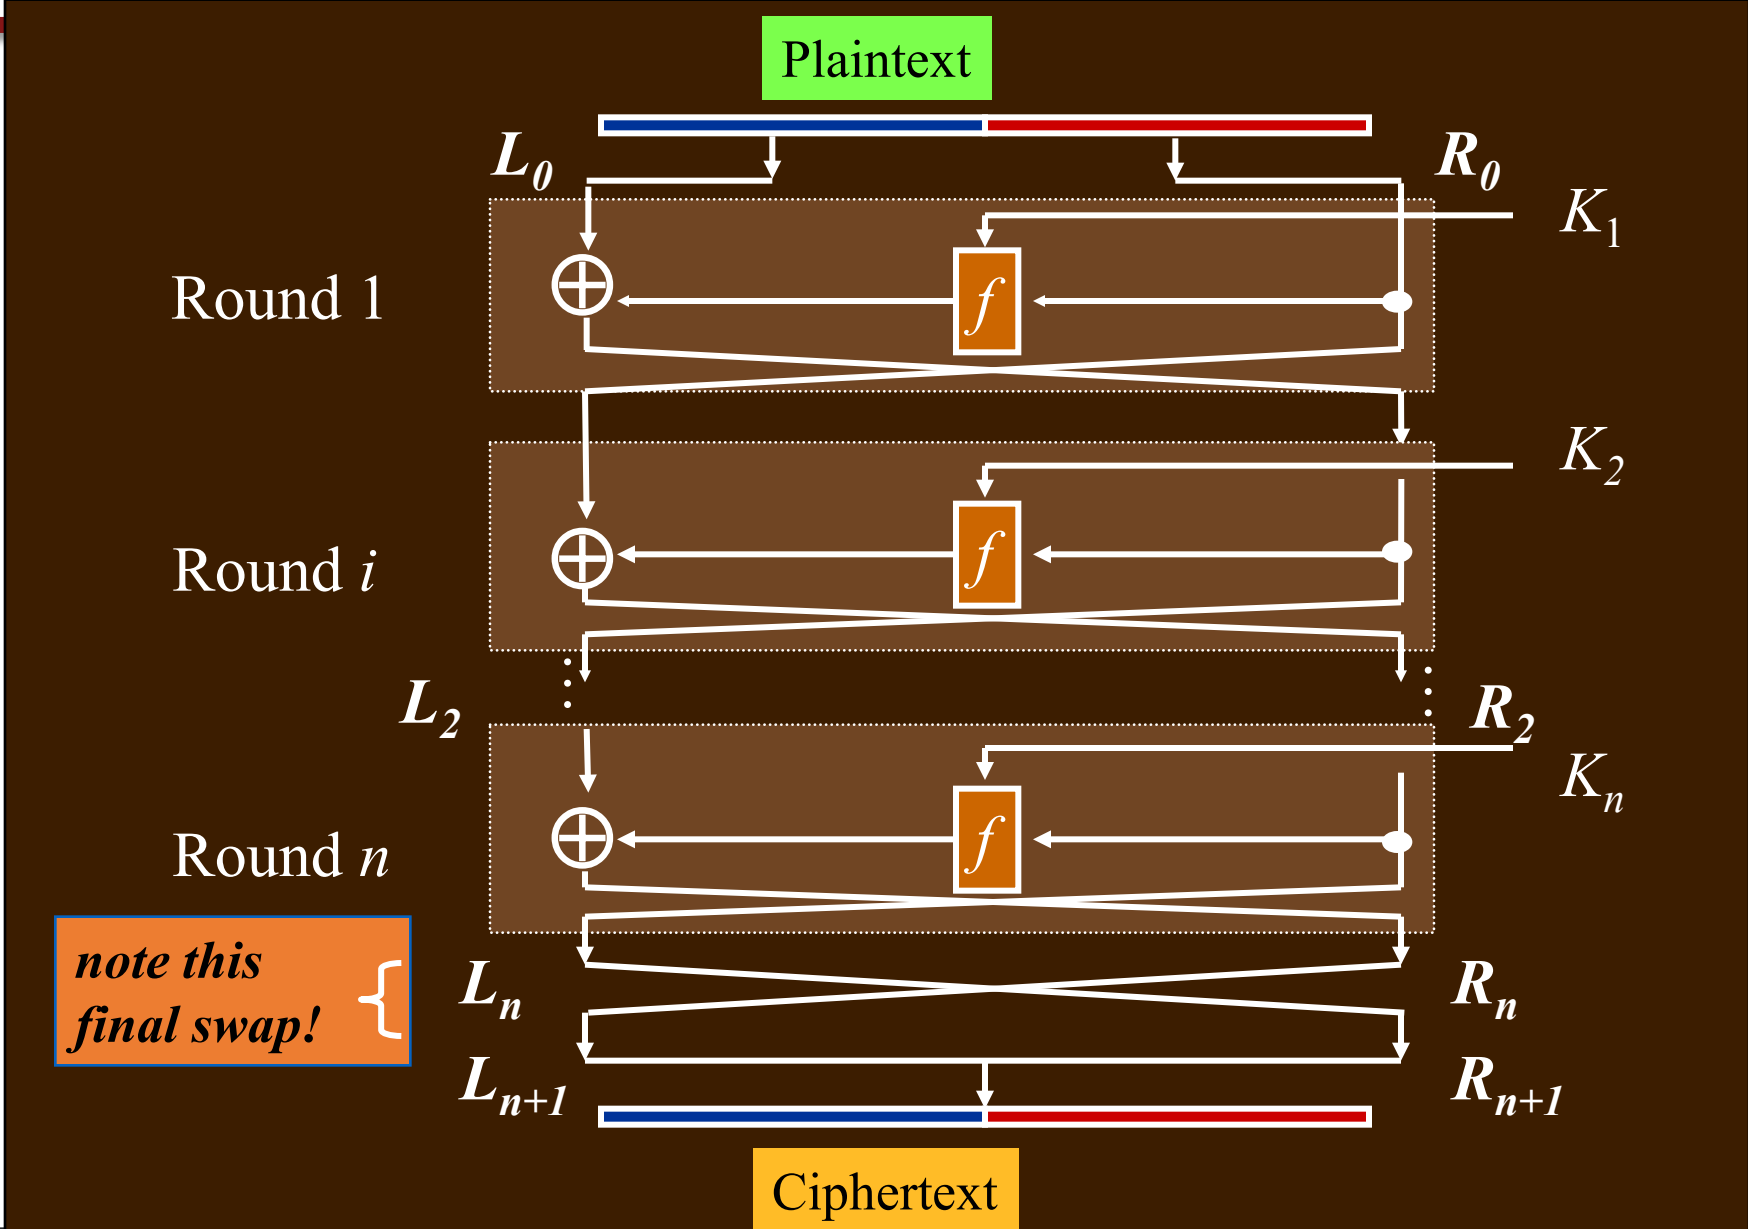

Key generation:  
subkey is the key

Scrambling function  
 $f(K, R_i) = K \oplus R_i$

Q: What's the output?

# COMPLETE FEISTEL CIPHER: ENCRYPTION

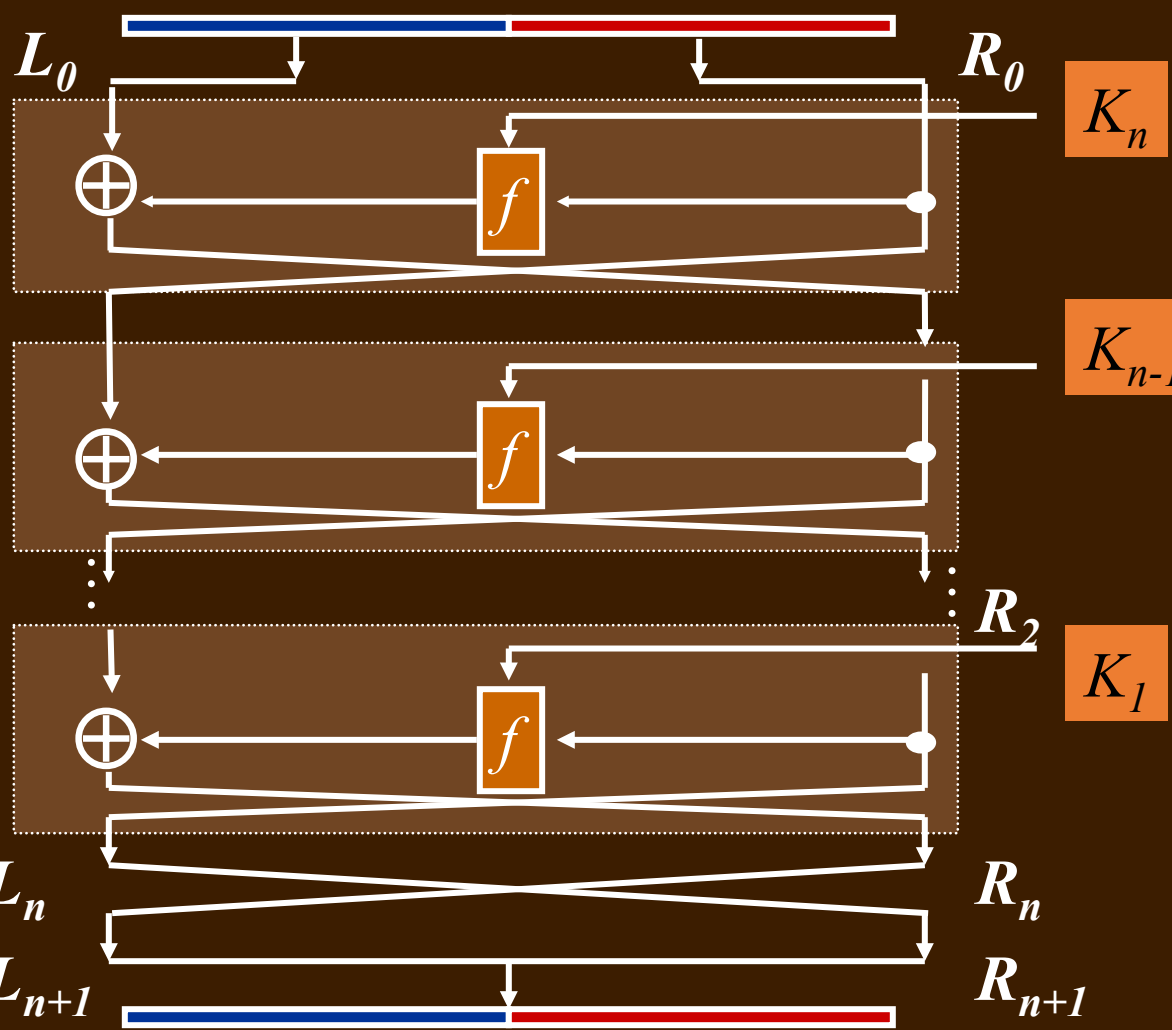

*note this final swap!*

# COMPLETE FEISTEL CIPHER: DECRYPTION

Ciphertext

*note this final swap!*

Plaintext

# PARAMETERS OF A FEISTEL CIPHER

- Block size
- Key size
- Number of rounds
- Subkey generation algorithm
- “Scrambling” function  $f$
